# **Machine Learning Engineer Nanodegree**

### **Model Evaluation & Validation**

## **Project 1: Predicting Boston Housing Prices**

Welcome to the first project of the Machine Learning Engineer Nanodegree! In this notebook, some template code has already been written. You will need to implement additional functionality to successfully answer all of the questions for this project. Unless it is requested, do not modify any of the code that has already been included. In this template code, there are four sections which you must complete to successfully produce a prediction with your model. Each section where you will write code is preceded by a **STEP X** header with comments describing what must be done. Please read the instructions carefully!

In addition to implementing code, there will be questions that you must answer that relate to the project and your implementation. Each section where you will answer a question is preceded by a **QUESTION X** header. Be sure that you have carefully read each question and provide thorough answers in the text boxes that begin with "**Answer:**". Your project submission will be evaluated based on your answers to each of the questions.

A description of the dataset can be found <u>here (https://archive.ics.uci.edu/ml/datasets/Housing)</u>, which is provided by the **UCI Machine Learning Repository**.

# **Getting Started**

To familiarize yourself with an iPython Notebook, **try double clicking on this cell**. You will notice that the text changes so that all the formatting is removed. This allows you to make edits to the block of text you see here. This block of text (and mostly anything that's not code) is written using <u>Markdown (http://daringfireball.net/projects/markdown/syntax)</u>, which is a way to format text using headers, links, italics, and many other options! Whether you're editing a Markdown text block or a code block (like the one below), you can use the keyboard shortcut **Shift + Enter** or **Shift + Return** to execute the code or text block. In this case, it will show the formatted text.

Let's start by setting up some code we will need to get the rest of the project up and running. Use the keyboard shortcut mentioned above on the following code block to execute it. Alternatively, depending on your iPython Notebook program, you can press the **Play** button in the hotbar. You'll know the code block executes successfully if the message "Boston Housing dataset loaded successfully!" is printed.

```
In [7]: # Importing a few necessary libraries
        import numpy as np
        import matplotlib.pyplot as pl
        from sklearn import datasets
        from sklearn.tree import DecisionTreeRegressor
        # Make matplotlib show our plots inline (nicely formatted in the no
        tebook)
        %matplotlib inline
        # Create our client's feature set for which we will be predicting a
        selling price
        CLIENT FEATURES = [[11.95, 0.00, 18.100, 0, 0.6590, 5.6090, 90.00,
        1.385, 24, 680.0, 20.20, 332.09, 12.13]]
        # Load the Boston Housing dataset into the city data variable
        city data = datasets.load boston()
        # Initialize the housing prices and housing features
        housing prices = city data.target
        housing features = city data.data
        print "Boston Housing dataset loaded successfully!"
```

Boston Housing dataset loaded successfully!

# Statistical Analysis and Data Exploration

In this first section of the project, you will quickly investigate a few basic statistics about the dataset you are working with. In addition, you'll look at the client's feature set in CLIENT\_FEATURES and see how this particular sample relates to the features of the dataset. Familiarizing yourself with the data through an explorative process is a fundamental practice to help you better understand your results.

## Step 1

In the code block below, use the imported numpy library to calculate the requested statistics. You will need to replace each None you find with the appropriate numpy coding for the proper statistic to be printed. Be sure to execute the code block each time to test if your implementation is working successfully. The print statements will show the statistics you calculate!

```
In [82]: # Number of houses in the dataset
         total houses = housing features.shape[0]
         # Number of features in the dataset
         total features = housing features.shape[1]
         # Minimum housing value in the dataset
         minimum price = np.amin(housing prices)
         # Maximum housing value in the dataset
         maximum price = np.amax(housing prices)
         # Mean house value of the dataset
         mean price = np.mean(housing prices)
         # Median house value of the dataset
         median price = np.median(housing prices)
         # Standard deviation of housing values of the dataset
         std dev = np.std(housing prices)
         # Show the calculated statistics
         print "Boston Housing dataset statistics (in 1000's:\n"
         print "Total number of houses:", total_houses
         print "Total number of features:", total features
         print "Minimum house price:", minimum price
         print "Maximum house price:", maximum price
         print "Mean house price: {0:.3f}".format(mean_price)
         print "Median house price:", median price
         print "Standard deviation of house price: {0:.3f}".format(std dev)
```

#### Boston Housing dataset statistics (in \$1000's):

```
Total number of houses: 506
Total number of features: 13
Minimum house price: 5.0
Maximum house price: 50.0
Mean house price: 22.533
Median house price: 21.2
Standard deviation of house price: 9.188
```

**Question 1** 

As a reminder, you can view a description of the Boston Housing dataset here (https://archive.ics.uci.edu/ml/datasets/Housing), where you can find the different features under

Attribute Information. The MEDV attribute relates to the values stored in our housing prices variable,

so we do not consider that a feature of the data.

Of the features available for each data point, choose three that you feel are significant and give a brief

description for each of what they measure.

Remember, you can double click the text box below to add your answer!

**Answer:** 

TAX: full-value property-tax rate per \$10,000. I think this would have a direct correlation with the propery

values per area.

CRIM: per capita crime rate by town. I would guess that higher crime is an indicator for lower price,

except in areas affected by gentrification.

LSTAT: percent lower status of the population. An increasing number of low-income residents should be

an indicator of decreasing home values.

**Question 2** 

Using your client's feature set CLIENT FEATURES, which values correspond with the features you've

chosen above?

Hint: Run the code block below to see the client's data.

In [9]: print CLIENT FEATURES

[[11.95, 0.0, 18.1, 0, 0.659, 5.609, 90.0, 1.385, 24, 680.0, 20.

2, 332.09, 12.1311

**Answer:** 

TAX: 680.0 CRIM: 11.95 LSTAT: 12.13

file:///Users/mroyal/Downloads/boston\_housing.html

4/17

# **Evaluating Model Performance**

In this second section of the project, you will begin to develop the tools necessary for a model to make a prediction. Being able to accurately evaluate each model's performance through the use of these tools helps to greatly reinforce the confidence in your predictions.

## Step 2

In the code block below, you will need to implement code so that the shuffle\_split\_data function does the following:

- Randomly shuffle the input data x and target labels (housing values) y.
- Split the data into training and testing subsets, holding 30% of the data for testing.

If you use any functions not already acessible from the imported libraries above, remember to include your import statement below as well!

Ensure that you have executed the code block once you are done. You'll know the shuffle\_split\_data function is working if the statement "Successfully shuffled and split the data!" is printed.

```
In [37]: # Put any import statements you need for this code block here
         from sklearn import cross validation as cv
         def shuffle split data(X, y):
             """ Shuffles and splits data into 70% training and 30% testing
         subsets,
                 then returns the training and testing subsets. """
             # Shuffle and split the data
             X train, X test, y train, y test = cv.train test split(housing
         features, housing prices, test size=.3)
             # Return the training and testing data subsets
             return X train, y train, X test, y test
         # Test shuffle split data
         try:
             X train, y train, X test, y test = shuffle split data(housing f
         eatures, housing prices)
             print "Successfully shuffled and split the data!"
         except:
             print "Something went wrong with shuffling and splitting the da
         ta."
                             0.00000000e+00
                                              1.81000000e+01 ...,
            1.00623000e+01
                                                                    2.020
         [ [
         00000e+01

                                                                    1.490
         00000e+01
```

4.85000000e+00]]

## **Question 3**

Why do we split the data into training and testing subsets for our model?

Successfully shuffled and split the data!

3.96900000e+02

#### **Answer:**

To prevent overfitting. If we test on the same data we used for training, we would end up with a model that is biased to the training data, and it would not predict unknown data well.

## Step 3

In the code block below, you will need to implement code so that the performance\_metric function does the following:

 Perform a total error calculation between the true values of the y labels y\_true and the predicted values of the y labels y predict.

You will need to first choose an appropriate performance metric for this problem. See <u>the sklearn metrics</u> <u>documentation (http://scikit-learn.org/stable/modules/classes.html#sklearn-metrics-metrics)</u> to view a list of available metric functions. **Hint:** Look at the question below to see a list of the metrics that were covered in the supporting course for this project.

Once you have determined which metric you will use, remember to include the necessary import statement as well!

Ensure that you have executed the code block once you are done. You'll know the performance\_metric function is working if the statement "Successfully performed a metric calculation!" is printed.

```
In [97]: # Put any import statements you need for this code block here
         from sklearn import metrics
         def performance metric(y true, y predict):
             """ Calculates and returns the total error between true and pre
         dicted values
                 based on a performance metric chosen by the student.
             error = metrics.mean absolute error(y true, y predict)
             return error
         # Test performance metric
         try:
             total error = performance metric(y train, y train)
             print "Successfully performed a metric calculation!"
         except Exception as e:
             print e
             print "Something went wrong with performing a metric calculatio
         n."
```

Successfully performed a metric calculation!

### **Question 4**

Which performance metric below did you find was most appropriate for predicting housing prices and analyzing the total error. Why?

- Accuracy
- Precision
- Recall
- F1 Score
- Mean Squared Error (MSE)
- Mean Absolute Error (MAE)

#### **Answer:**

I think them mean absolute error (MAE) is most appropriate. Accuracy, precision, recall and F1 score all apply to binary classification. The mean absolute error is a direct measure of prediction errors. If we wanted to give higher weight to larger errors, we could use the mean squared error (MSE) performance metric.

## Step 4 (Final Step)

In the code block below, you will need to implement code so that the fit\_model function does the following:

- Create a scoring function using the same performance metric as in Step 2. See the <u>sklearn</u> make\_scorer documentation (http://scikit-learn.org/stable/modules/generated/sklearn.metrics.make scorer.html).
- Build a GridSearchCV object using regressor, parameters, and scoring\_function. See
  the sklearn documentation on GridSearchCV (http://scikitlearn.org/stable/modules/generated/sklearn.grid search.GridSearchCV.html).

When building the scoring function and GridSearchCV object, be sure that you read the parameters documentation thoroughly. It is not always the case that a default parameter for a function is the appropriate setting for the problem you are working on.

Since you are using sklearn functions, remember to include the necessary import statements below as well!

Ensure that you have executed the code block once you are done. You'll know the fit\_model function is working if the statement "Successfully fit a model to the data!" is printed.

```
In [98]: # Put any import statements you need for this code block
         from sklearn.metrics import make scorer
         from sklearn.grid search import GridSearchCV
         def fit model(X, y):
              """ Tunes a decision tree regressor model using GridSearchCV on
         the input data X
                 and target labels y and returns this optimal model. """
             # Create a decision tree regressor object
             regressor = DecisionTreeRegressor()
             # Set up the parameters we wish to tune
             parameters = \{ \max depth': (1,2,3,4,5,6,7,8,9,10) \}
             # Make an appropriate scoring function
             scoring_function = make_scorer(performance_metric, greater_is_b
         etter=False)
             # Make the GridSearchCV object
             reg = GridSearchCV(regressor, parameters, scoring=scoring funct
         ion)
             # Fit the learner to the data to obtain the optimal model with
         tuned parameters
             reg.fit(X, y)
             # Return the optimal model
             return reg.best estimator
         # Test fit model on entire dataset
         try:
             reg = fit model(housing features, housing prices)
             print "Successfully fit a model!"
         except:
             print "Something went wrong with fitting a model."
```

Successfully fit a model!

## **Question 5**

What is the grid search algorithm and when is it applicable?

#### **Answer:**

The grid search algorithm is a way of exhaustively applying a regression algorithm to a training data set, scoring each member of the testing data set based on a given performance metric and returning the settings that produce the best score. Grid search is applicable in cases where the dimentionality of the domain is low, since its performance is exponential with respect to the number of parameters.

### **Question 6**

What is cross-validation, and how is it performed on a model? Why would cross-validation be helpful when using grid search?

#### **Answer:**

Cross-validation is an alternative to simply splitting the data into training and validation sets, which can still be subject to bias as we tune our model's parameters.

It is performed on a model by learning and then testing against multiple (or all!) possible ways to partition the data into training/test sets. For example, k-fold cross-validation, involves randomly creating k partitions of the data and iterating k times, using a different partition for validation each time and all other partitions for training.

Cross-validation is important when using grid search to ensure that our algorithm produces an estimator that is as general as possible given the input data.

# **Checkpoint!**

You have now successfully completed your last code implementation section. Pat yourself on the back! All of your functions written above will be executed in the remaining sections below, and questions will be asked about various results for you to analyze. To prepare the **Analysis** and **Prediction** sections, you will need to intialize the two functions below. Remember, there's no need to implement any more code, so sit back and execute the code blocks! Some code comments are provided if you find yourself interested in the functionality.

```
In [99]: def learning curves(X train, y train, X test, y test):
              """ Calculates the performance of several models with varying s
         izes of training data.
                 The learning and testing error rates for each model are the
         n plotted. """
             print "Creating learning curve graphs for max depths of 1, 3,
         6, and 10. . . "
             # Create the figure window
             fig = pl.figure(figsize=(10,8))
             # We will vary the training set size so that we have 50 differe
         nt sizes
             sizes = np.rint(np.linspace(1, len(X train), 50)).astype(int)
             train err = np.zeros(len(sizes))
             test err = np.zeros(len(sizes))
             # Create four different models based on max depth
             for k, depth in enumerate([1,3,6,10]):
                 for i, s in enumerate(sizes):
                     # Setup a decision tree regressor so that it learns a t
         ree with max depth = depth
                     regressor = DecisionTreeRegressor(max depth = depth)
                     # Fit the learner to the training data
                     regressor.fit(X train[:s], y train[:s])
                     # Find the performance on the training set
                     train err[i] = performance metric(y train[:s], regresso
         r.predict(X train[:s]))
                     # Find the performance on the testing set
                     test_err[i] = performance_metric(y_test, regressor.pred
         ict(X test))
                 # Subplot the learning curve graph
                 ax = fig.add subplot(2, 2, k+1)
                 ax.plot(sizes, test err, lw = 2, label = 'Testing Error')
                 ax.plot(sizes, train err, lw = 2, label = 'Training Error')
                 ax.legend()
                 ax.set title('max depth = \$s'\$(depth))
                 ax.set xlabel('Number of Data Points in Training Set')
                 ax.set ylabel('Total Error')
                 ax.set_xlim([0, len(X_train)])
             # Visual aesthetics
             fig.suptitle('Decision Tree Regressor Learning Performances', f
         ontsize=18, y=1.03)
             fig.tight layout()
             fig.show()
```

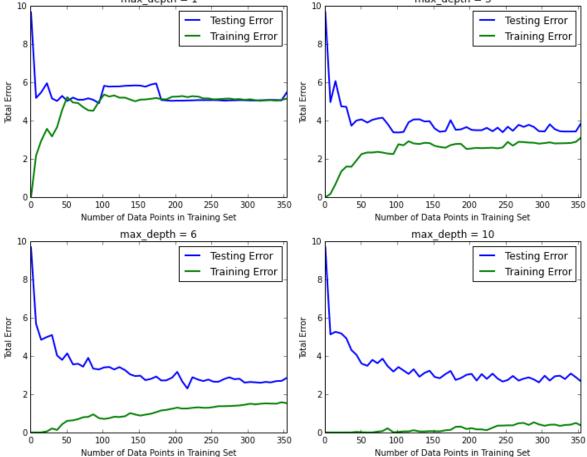

```
def model complexity(X train, y train, X test, y test):
In [103]:
              """ Calculates the performance of the model as model complexity
          increases.
                  The learning and testing errors rates are then plotted. """
              print "Creating a model complexity graph. . . "
              # We will vary the max depth of a decision tree model from 1 to
          14
              max depth = np.arange(1, 14)
              train err = np.zeros(len(max depth))
              test err = np.zeros(len(max depth))
              for i, d in enumerate(max depth):
                  # Setup a Decision Tree Regressor so that it learns a tree
          with depth d
                  regressor = DecisionTreeRegressor(max depth = d)
                  # Fit the learner to the training data
                  regressor.fit(X_train, y_train)
                  # Find the performance on the training set
                  train err[i] = performance metric(y train, regressor.predic
          t(X train))
                  # Find the performance on the testing set
                  test err[i] = performance metric(y test, regressor.predict
          (X test))
              # Plot the model complexity graph
              pl.figure(figsize=(7, 5))
              pl.title('Decision Tree Regressor Complexity Performance')
              pl.plot(max depth, test err, lw=2, label = 'Testing Error')
              pl.plot(max depth, train err, lw=2, label = 'Training Error')

# **Analyzing Model Performance**

In this third section of the project, you'll take a look at several models' learning and testing error rates on various subsets of training data. Additionally, you'll investigate one particular algorithm with an increasing max\_depth parameter on the full training set to observe how model complexity affects learning and testing errors. Graphing your model's performance based on varying criteria can be beneficial in the analysis process, such as visualizing behavior that may not have been apparent from the results alone.

In [102]: learning\_curves(X\_train, y\_train, X\_test, y\_test)
Creating learning curve graphs for max\_depths of 1, 3, 6, and 10.

### **Question 7**

Choose one of the learning curve graphs that are created above. What is the max depth for the chosen model? As the size of the training set increases, what happens to the training error? What happens to the testing error?

#### **Answer:**

For the model with **max\_depth = 6**, as the size of the training set increases, the training error gradually increases and the testing error decreases.

## **Question 8**

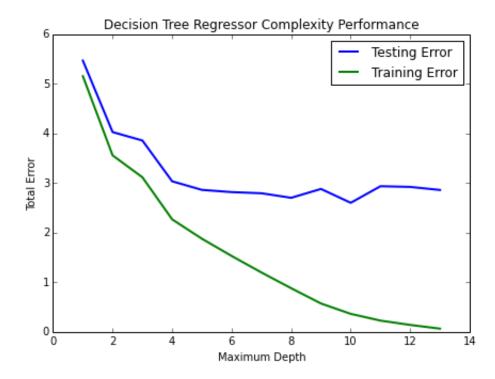

Look at the learning curve graphs for the model with a max depth of 1 and a max depth of 10. When the model is using the full training set, does it suffer from high bias or high variance when the max depth is 1? What about when the max depth is 10?

#### **Answer:**

With a max depth of 1, there is very high variance when using the full data set due to underfitting. A max depth of 10, on the other hand, has the opposite problem of overfitting, resulting in a model that's biased to the training data.

In [104]: model\_complexity(X\_train, y\_train, X\_test, y\_test)

Creating a model complexity graph. . .

### **Question 9**

From the model complexity graph above, describe the training and testing errors as the max depth increases. Based on your interpretation of the graph, which max depth results in a model that best generalizes the dataset? Why?

#### **Answer:**

As the max depth approaches 13, the training error approaches zero. The testing error levels off around  $max \ depth = 4$ . I think  $max \ depth = 4$  results in the model that best generalizes the data, because that's the max depth that suffers the least from bias or variance. The testing error is near its global minimum (indicating low variance) and the training error and testing error are very close (indicating low bias).

## **Model Prediction**

In this final section of the project, you will make a prediction on the client's feature set using an optimized model from fit\_model. When applying grid search along with cross-validation to optimize your model, it would typically be performed and validated on a training set and subsequently evaluated on a **dedicated test set**. In this project, the optimization below is performed on the *entire dataset* (as opposed to the training set you made above) due to the many outliers in the data. Using the entire dataset for training provides for a less volatile prediction at the expense of not testing your model's performance.

To answer the following questions, it is recommended that you run the code blocks several times and use the median or mean value of the results.

### **Question 10**

Using grid search on the entire dataset, what is the optimal max\_depth parameter for your model? How does this result compare to your intial intuition?

Hint: Run the code block below to see the max depth produced by your optimized model.

```
In [107]: print "Final model has an optimal max_depth parameter of", reg.get_
    params()['max_depth']

Final model has an optimal max depth parameter of 4
```

#### **Answer:**

Ooh, the optimized model has  $max\_depth = 4$ , which matched my initial intuition. Hopefully my reasoning was sound as well, rather than just a coincidence.

## **Question 11**

With your parameter-tuned model, what is the best selling price for your client's home? How does this selling price compare to the basic statistics you calculated on the dataset?

**Hint:** Run the code block below to have your parameter-tuned model make a prediction on the client's home.

```
In [110]: sale_price = reg.predict(CLIENT_FEATURES)
    print "Predicted value of client's home: {0:.3f}".format(sale_price
       [0])
```

Predicted value of client's home: 21.630

#### **Answer:**

The predicted value of the client's home is \$216,300, about 96% of the mean (\$225,330) and about 102% of the median (\$212,000).

# **Question 12 (Final Question):**

In a few sentences, discuss whether you would use this model or not to predict the selling price of future clients' homes in the Greater Boston area.

#### **Answer:**

I would for sure not use this model *alone* for a couple of reasons. The error on the test data is still somewhat high. There are also subjective property-specific features that contribute to home value that are not included in this model (for example, additions, view, etc). But it's a good start!
